Chapter 22
Analyzing by Groups

In SAS/INSIGHT software, you can use a group variable to process your data separately for each value of the group variable. You can use multiple group variables to process your data separately for each unique combination of grouping values.

Figure 22.1. Analyzing by Groups
Using Group Variables

You can learn more about the distribution of drilling times by constructing a distribution analysis using group variables.

⇒ Choose Analyze:Distribution (Y).

This displays the distribution variables dialog.

⇒ In the dialog, select DRILTIME, then click the Y button.
This assigns DRILTIME the required Y role.

⇒ Select METHOD and REP, and click the Group button.
This assigns METHOD and REP the Group role. You can scroll the Group list to see both variables. Because there are two values for Method and three values for Rep, this produces six groups.

⇒ Click OK to create the distribution window, as shown in Figure 22.3.

The distribution window shows detailed information on the distributions, including box plots, histograms, moments, and quantiles. At the top of the distribution window is a table indicating the unique combination of values of the two group variables. You can scroll the distribution window to the right to see other levels.
Figure 22.3. Distribution Window with Group Variables
Comparing Groups by Copying Windows

Because there are six groups, it is difficult to compare two groups side by side. Also, the axes are scaled to fit the data, so by default graphs use different axes.

To compare two groups side by side using the same axes, you can create a copy of the distribution analysis, set tick marks, and align the axes.

Choose **Edit:Windows:Copy Window** in the Distribution analysis.
This creates a copy of the distribution analysis.

Move the two analyses side by side.
Now you can scroll the windows horizontally to compare any two groups. Figure 22.4 shows the first and last groups side by side.

![Figure 22.4. Comparing Distribution Analyses](image)

The **Moments** and **Quantiles** tables below the histograms present statistics you can compare. The box plots and histograms, however, are difficult to compare because they use different axes. You can customize the axes with the following steps.
Select **DRILTIME** in the first distribution window.

Choose **Ticks** from the histogram pop-up menu in the first window.
This displays the **Ticks** dialog.

Make the adjustments shown in the following figure, and click the OK button.
This scales the **DRILTIME** axis for all histograms.

![Figure 22.5. Ticks Dialog](image)

Repeat these steps for the box plots in the first window.
This scales the **DRILTIME** axis for all box plots.

Repeat these steps for the second window.
Now you can compare box plots and histograms in both windows.
Figure 22.6. Comparing Distribution Analyses

† Note: By default, axes in SAS/INSIGHT software are scaled to fit the data. You can choose **Edit:Windows:Align** in any analysis window to align axes that use the same variable. Aligning affects only the axis scale, not the tick marks. When aligning histogram axes as in the preceding example, you should use the Ticks dialog to give histogram bars the same width and position.

Setting Default Group Variables

Often you will want to assign Group roles to the same group variables throughout a SAS/INSIGHT session. You can save time by setting default Group roles in the data window so that you do not have to set them in every variables dialog.

To set default Group roles for SASUSER.MINING, follow these steps.

1. Choose Define Variables from the data pop-up menu. This displays the Define Variables dialog.
2. In the dialog, click on METHOD, then click on Group under Default Role. This assigns the Group role to the METHOD variable.
3. Click the Apply button. This assigns the Group role to METHOD but leaves the Define Variables window open so that you can assign roles to other variables as well.
4. Click on REP, then click on Group under Default Role. This assigns the Group role to the REP variable as well.
5. Click the OK button to close the dialog. The Group role now appears above both METHOD and REP in the data window.
Chapter 22. Analyzing by Groups

Figure 22.8. Two Group Roles Assigned

*Note:* Order is significant. The order in which you assign roles is the order in which your group variables are used in analyses.

Choose Analyze: Box Plot/Mosaic Plot (Y).

Notice that the Group roles are already assigned. Only METHOD is visible, but you can scroll the Group list to see REP.

Figure 22.9. Box Plot Variables Dialog

Now every analysis you create will use the default Group roles you assigned in the data window. If you want to create an analysis without these variables, you can select them in the variables dialog and click the Remove button.
Formatting Group Variables

Usually, SAS formats in SAS/INSIGHT software determine only how data are visually displayed. Group variables, however, can use SAS formats to combine different values into a larger group. For example, suppose you are interested only in approximate depths, not in the exact values of `DEPTH`. You can use a format to combine the values of `DEPTH` into three groups:

- `DEPTH \leq 100`
- `100 < DEPTH \leq 300`
- `300 < DEPTH`

Once you have assigned this format to `DEPTH`, you can assign `DEPTH` a Group role and use it as described earlier in this section. Each use of `DEPTH` creates three groups containing values in the three ranges you specified.
